

O A A D

Open Source Software **Agentic AI** **DevSecOps**

The enterprise platform that replaces the COTS business capability stack
with OSS systems made enterprise-viable through agentic AI and DevSecOps governance.

OSS already existed. Agentic AI made it enterprise-ready.

A Platform. Not a Product.

Open Source Software

Every business capability domain has a mature OSS alternative today: iTop, SuiteCRM, Odoo, ERPNext, GitLab, Mattermost, Metabase, Wazuh. OAAD curates and operates them. The software is not built. It is selected, deployed, and owned.

Agentic AI: Orchestration Fabric

Agents are the adaptive orchestration and knowledge layer above deterministic integration primitives. They route, interpret, coordinate, monitor, and encode. They do not replace the integration engineering beneath them.

Agentic AI: Lifecycle Governance

Every OAAD agent carries full lifecycle governance: prompt versioning, CI/CD promotion gates, evaluation frameworks, HITL checkpoints, identity, delegated authority, and LLM-native observability.

DevSecOps

DevSecOps is not a process bolted on top. It is the operational spine of OAAD. Agent identity, delegated authority, audit attribution, and risk-calibrated controls are architecture, not policy.

Agentic Platforms Are the New Enterprise Control Plane

The enterprise software market is undergoing a structural transition. The agentic layer is coming. The question is who will own it, and who will benefit from the intelligence it accumulates.

The Build-vs-Buy Calculus Just Changed

For thirty years, buying COTS was the safe default. Vendor risk meant license cost. That calculus assumed software was static. Agentic platforms break the assumption.

The Old Calculus

Vendor risk meant license cost, upgrade cycles, and integration debt. Build risk meant engineering capacity, time to value, and ongoing maintenance. Buy usually won because software was a tool, not a learning system.

The New Variable

Agentic platforms encode institutional intelligence as they operate. Every workflow refined, every edge case handled, every escalation pattern learned becomes platform value. That value compounds over time, with use.

Where the Value Accrues

When the platform is vendor-owned, the compounding happens inside their schema. Your competitors using the same vendor benefit from your operational learning. The moat you are building belongs to the vendor.

What This Reframes

Buying COTS is no longer a cost-vs-cost trade. It is a question of whether the intelligence your enterprise generates strengthens your position or someone else's. Ownership is now a competitive variable, not a procurement preference.

Salesforce Agentforce: Right Architecture, Wrong Owner

Salesforce is not wrong because it is architecturally weak. Salesforce is dangerous because it is architecturally strong and vendor-owned. It is the clearest proof-of-concept for OAAD, and the clearest warning about where the moat accrues.

What Salesforce gets right

- Governed data layer (Informatica + Data 360) as grounded agent context
- Deterministic workflow + LLM reasoning hybrid: Agentforce Script combines programmatic control with flexible reasoning
- Agent lifecycle: build, test, deploy, observe, refine as platform strategy
- Governance, audit, HITL framed as enterprise differentiator
- Model flexibility: OpenAI, Anthropic, Gemini as interchangeable engines

What this proves about OAAD

- Every architecture capability Salesforce builds, OAAD builds on OSS the enterprise owns
- Intelligence moat accrues to Salesforce structurally, not to you
- Agent definitions, business logic, process memory encoded inside their schema
- Governance covers Salesforce workflows; the broader enterprise gap remains
- Salesforce validates the pattern. OAAD shifts the ownership.

Salesforce builds this platform and licenses access to you. OAAD builds it on OSS and gives you ownership.

Three Models. One Compounds.

TRADITIONAL COTS

ServiceNow · SAP · Workday · Salesforce

Ownership

Vendor

Business Logic

Trapped in vendor schema

Intelligence Moat

Accrues to vendor

Differentiation

None: same product, every competitor

Integration

Vendor's integration bus

AI Strategy

Copilot bolted on top

Cost Model

Perpetual license + PS army

Workforce

Admins and configurers

VENDOR AGENTIC PLATFORM

Salesforce Agentforce · MS Copilot · ServiceNow AI

Ownership

Vendor (new layer, same trap)

Business Logic

Trapped in vendor agent schema

Intelligence Moat

Accrues to vendor, again

Differentiation

Minimal: within vendor bounds

Integration

MCP/MuleSoft, vendor-brokered

AI Strategy

AI-native UI, legacy substrate

Cost Model

Higher licensing + agent consulting

Workforce

Prompt engineers in vendor sandbox (capped)

OAAD PLATFORM

OSS Stack · Agentic Fabric · DevSecOps Governance

Ownership

Enterprise, fully

Business Logic

Versioned agents the enterprise owns

Intelligence Moat

Accrues to the enterprise

Differentiation

Compounding: encodes your uniqueness

Integration

Agentic fabric above deterministic layer

AI Strategy

AI-native from substrate to capability

Cost Model

Platform investment, zero license rent

Workforce

Platform engineers + agent architects (scarce)

The Alternatives Already Exist. Today.

Every major COTS domain has a mature OSS alternative. The gap was never capability. It was integration, operations, and governance at enterprise scale. OAAD closes that gap.

DOMAIN	COTS DISPLACED	OSS ALTERNATIVE (EXISTS TODAY)	OAAD AGENTIC LAYER	PHASE
IT Service Mgmt	ServiceNow	iTop / GLPI / Zammad	Incident triage, change orchestration, CMDB sync, self-healing ops	1
CRM & Sales	Salesforce	SuiteCRM / Twenty / Odoo CRM	Lead intelligence, account context, pipeline automation, follow-up	2
ERP & Finance	SAP / Oracle	Odoo / ERPNext / Dolibarr	Procurement flows, financial close, inventory, supply chain agents	3
HR & Workforce	Workday / SuccessFactors	OrangeHRM / Sentrifugo / Odoo HR	Onboarding automation, policy agents, workforce analytics	2
DevOps & SDLC	Jira / ServiceNow SPM	GitLab / Gitea / Taiga / Plane	Agentic CI/CD, sprint automation, code review, release intelligence	1
Collab & Comms	M365 / Teams Copilot	Mattermost / Rocket.Chat / Nextcloud	Meeting intelligence, action routing, knowledge agents	1
Data & Analytics	Tableau / PowerBI	Metabase / Apache Superset / Redash	NL analytics queries, anomaly detection, automated reporting	2
Security & GRC	Splunk / Archer / Qualys	Wazuh / OpenSearch / GVM / Eramba	Threat hunting agents, compliance automation, risk scoring	3

What OAAD Doesn't Claim to Replace

A credible displacement thesis names its limits. OAAD targets the COTS business capability stack. Several enterprise workload categories sit outside that scope by design.

Regulated Financial Systems

Payroll, treasury, tax compliance, and audit-bound general ledger systems carry vendor certifications and regulatory accreditations that OSS rarely matches today. Displacement here is a long-horizon play, not a Phase 0 target.

Industry-Specific Regulated Workflows

FDA-validated systems (clinical, pharma manufacturing), HIPAA-bound EHR, ITAR/CMMC-bound defense workflows, FedRAMP-bound government systems. The accreditation cost dominates the platform cost; vendor absorption is usually the right answer.

Hyperscaler Foundational Services

Identity (Entra/Okta), email infrastructure (Exchange/Workspace), and productivity suites where switching cost vastly exceeds platform cost. OAAD integrates with these systems; it does not replace them.

Specialized Engineering Tools

CAD, EDA, MBSE authoring tools, specialized scientific computing. These are professional instruments with deep domain integration, not business capability platforms. Outside OAAD scope by design.

OSS Capabilities + Agentic Fabric + Governance

OSS BUSINESS CAPABILITY LAYER

iTop · SuiteCRM · Odoo · ERPNext · OrangeHRM · GitLab · Mattermost · Metabase · Wazuh

Mature OSS systems covering every major COTS domain. Already exist, proven, zero license cost

OAAD AGENTIC ORCHESTRATION FABRIC

Adaptive orchestration above deterministic integration · Institutional knowledge encoding · RAG on enterprise data · Multi-agent decomposition

Agents route, interpret, coordinate, monitor, and encode. They do not replace the deterministic integration layer beneath them

DETERMINISTIC INTEGRATION LAYER

API gateway · Event bus (Kafka/NATS) · Identity broker (Keycloak) · Schema registry · OPA policy enforcement · OpenTelemetry observability

Transaction integrity, latency guarantees, rollback semantics, audit contracts. Not replaced by agents; governed alongside them

DEVSECOPS GOVERNANCE & OBSERVABILITY LAYER

Agent identity & delegated authority · Prompt CI/CD · HITL checkpoints · SIEM/GRC integration · LLM-native observability · Audit trails

Every agent action is attributable, versioned, and auditable, integrated with enterprise IAM, PAM, and GRC from day one

INFRASTRUCTURE LAYER

Kubernetes · OSS model serving (Llama, Mistral, Qwen) · Vector stores · Data platform · DevSecOps toolchain

Governance Requires a Precise Authority Taxonomy

Without separating these dimensions, OAAD reproduces the governance collapse it criticizes in vendor platforms. Each dimension requires its own control, audit, and policy surface.

Agent Identity

What the agent IS: unique identity, persona, version, scope, and owner

Operator Identity

WHO invoked or owns the agent: human or system principal that bears accountability

Delegated Authority

WHAT the agent may do: explicit grant of permitted actions, bounded and time-limited

Tool Authority

WHAT each connected system permits: per-system capability grants, not assumed from identity

Data Authority

WHAT data the agent may retrieve, infer from, or act on: governed by data classification

Execution Authority

WHAT actions it may perform autonomously vs. those requiring HITL escalation

Persona

HOW the agent communicates: communication profile, tone, disclosure posture

Audit Attribution

HOW responsibility is traced: immutable log linking every action to agent + operator + grant

Replace License Rent With Platform Investment

The OAAD case is not "free OSS replaces paid COTS." The credible version: OAAD trades recurring vendor rent for owned platform engineering capacity and a compounding institutional intelligence asset.

COST BUCKET	COTS MODEL	OAAD MODEL
Software license	High: perpetual or subscription	Zero: OSS is free
Professional services	High: vendor PS army	Moderate: platform engineering team
Integration engineering	Moderate: vendor bus + connectors	Moderate: OSS toolchain + agent layer
Admin/config workforce	High: vendor-specialist headcount	Lower: platform engineers + agent architects
AI/model costs	Bundled in license (opaque)	Explicit: OSS model hosting + inference
Security accreditation	Vendor-certified (absorbed)	Enterprise-owned: first-class OAAD discipline
Migration + change mgmt	Per-upgrade cycle (ongoing)	One-time per domain + continuous DevSecOps
Institutional intelligence	Accrues to vendor	Accrues to enterprise; compounds over time

Assumptions note: 60-80% license reduction and 10x velocity are directional targets. Full business case requires baseline COTS spend by domain, engineering headcount, model hosting costs, migration reserves, and break-even window, all developed in Phase 0 discovery.

Who Owns It, Runs It, Fixes It at 2am.

"Platform team plus agents" describes a direction. An operating model names owners, escalation paths, and accountability. Executives need that chain before they will fund a platform.

TIER 0

Self-Healing Automation

- Agents execute automated runbooks for known failure modes
- Self-healing ops: restart, rebalance, reroute, alert
- OSS monitoring stack triggers remediation
- No human involvement for Tier 0 events

TIER 1

Platform Support Desk

- First human escalation for agent and OSS system issues
- Covers incident triage, access requests, anomalies
- Staffed by platform-trained operators with runbook authority
- SLA: 15-min acknowledgement, 2-hour P1 resolution

TIER 2

Domain Platform Engineers

- Deep technical owners per OSS domain
- Handle complex incidents, agent failures, OSS upgrades
- Own agent lifecycle: versioning, eval, promotion, deprecation
- SLA: 4-hour P1 response, same-day P2

TIER 3

OSS & Model Specialists

- OSS maintainer channels and commercial support contracts
- Model incident: rollback, disablement, version reversion
- Security incident: SOC/SIEM/GRC escalation, CISO accountability
- Architecture review for high-stakes agent deployments

Ownership Is a Discipline

When OAAD replaces COTS, the enterprise inherits responsibilities the vendor previously absorbed. Stated correctly, this is not a liability. It is the mechanism by which the enterprise builds an unreplicable capability moat.

Patch & Vulnerability Management

- CVE monitoring across all OSS components
- Automated dependency scanning in CI/CD pipeline
- SBOM generation and container provenance tracking
- Patch SLA: critical 24hr, high 7 days, medium 30 days

License & Supply Chain Compliance

- OSS license inventory and compatibility matrix
- Code-signing and provenance for all platform artifacts
- Maintainer health monitoring (bus factor, activity, forks)
- Fork strategy playbook for abandoned critical components

Upgrade & Migration Choreography

- Version upgrade runway: never more than 2 major releases behind
- Automated regression test suite gating every OSS upgrade
- Data migration playbooks per OSS domain
- Backup, disaster recovery, and RTO/RPO per capability

Agent Model Governance

- Model version pinning with explicit upgrade gates
- Prompt regression testing before any model version change
- Model risk assessment for each new agent capability
- Rollback and disablement runbooks for model incidents

Four Risks. Four Mitigations.

Ownership creates control, but it also creates responsibility. OAAD wins only if the enterprise is willing to become a serious platform operator. These are the four risks that require architectural responses, not just policies.

OSS Supply Chain & Lifecycle

Maintainer abandonment, CVE exposure, license drift, upgrade debt

MITIGATION:

OSS lifecycle governance as first-class platform discipline (see Slide 13)

Agent Governance Collapse

Agent sprawl, unconstrained authority, audit gap, prompt injection

MITIGATION:

Agent authority taxonomy enforced at platform level; no agent to production without governance gate

Support & Accountability Gap

"Who do I call when it breaks?" COTS provides this; OAAD must build it

MITIGATION:

Tiered operating model with named owners, SLAs, escalation paths, and war-room protocols (see Slide 12)

Migration Cost & Org Resistance

COTS entanglement runs deep; change management, retraining, and workflow disruption are real

MITIGATION:

Start with DevOps/SDLC: lowest COTS entanglement, highest engineering tolerance, measurable outcomes

What the Agentic Layer Actually Does

OAAD agents don't replace OSS systems or the deterministic integration layer. They make the stack enterprise-coherent: adaptive, self-monitoring, and institutionally intelligent.

Adaptive Orchestration

Agents coordinate workflows across OSS systems above deterministic integration primitives. iTop raises an incident; an agent correlates SuiteCRM context, GitLab history, and CMDB state, then routes via Mattermost, without custom middleware, but with deterministic API contracts underneath.

Operational Intelligence

Agents handle routine operations the PS army used to perform: monitoring, self-healing, configuration drift detection, capacity alerts, release coordination. The OAAD platform runs itself at steady state, within the boundaries set by Tier 0 runbooks.

Institutional Knowledge Engine

Every agent workflow encodes how your enterprise actually operates, not a vendor template. Process variants, edge cases, escalation paths, org-specific policies. That knowledge is versioned, owned, and compounds over time. COTS platforms encode knowledge for their next customer. OAAD encodes it for you.

Continuous Improvement Loop

OAAD agents observe their own performance against evaluation criteria, flag failure modes, and surface improvement candidates for human review through the promotion gate process. The platform improves with use. Improvement stays inside the enterprise boundary.

DevSecOps is the Operative Word

Without governance architecture, "self-managed" becomes technical debt with ambition.

Agent Identity & Authority

- Every agent: defined identity, persona, version, and scope
- Delegated authority separated from human identity
- Integrated with enterprise IAM, PAM, and OPA
- Agent actions carry immutable audit attribution

Lifecycle & Version Control

- Prompt versioning with semantic diff tracking
- CI/CD promotion gates before production deployment
- Evaluation frameworks run before every release
- Deprecation and retirement policies enforced

Risk & Compliance

- Risk-calibrated human-in-the-loop checkpoints
- SIEM and GRC integration by design, not retrofit
- Adversarial red-team requirements for high-stakes agents
- Regulatory compliance architecture from day one

DevOps First. Then the Enterprise.

DevOps/SDLC is the right first domain: lowest COTS entanglement, highest engineering tolerance, measurable outcomes (cycle time, MTTR, deployment frequency), and bounded agent risk before touching customer, finance, or regulated workflows.

01

FOUNDATION

0–6 Months

Platform team • Governance • DevOps pilot

- Mandate OAAD platform team with exec mandate and budget
- Deploy GitLab + Mattermost + Wazuh as DevOps substrate
- Build first OAAD agent crew: CI/CD, release intelligence
- Establish agent authority model and governance baseline
- Define Tier 0-3 operating model, SLAs, and success metrics

▶ **GATE: DevOps pilot live; cycle time, MTTR baselined**

02

EXPANSION

6–18 Months

Multi-domain OSS stack • COTS rationalization begins

- Expand OAAD to ITSM, Collab, and Data domains
- Begin COTS contract rationalization: first terminations
- Build cross-domain agent orchestration patterns
- Integrate with IAM, SIEM, GRC, and data catalog
- OSS lifecycle governance operational across all domains

▶ **GATE: 3+ domains live; first COTS contracts terminated**

03

OAAD-NATIVE

18–36 Months

Full OSS stack • Compounding moat • COTS minimized

- OAAD covers full business capability stack
- COTS limited to regulated workflows only
- Intelligence moat compounding inside enterprise
- Agent self-optimization with continuous evaluation
- Enterprise is a platform builder, not a license consumer

▶ **STATE: COTS minimized; intelligence moat compounding**

The Platform Starts With a Decision

1 Fund the OAAD Platform Team

Name an internal owner with executive mandate and budget. Not a project. Not a vendor engagement. A product team that owns OAAD as a first-class enterprise asset with a defined operating model.

2 Authorize Phase 0 Discovery

Commission a 4-week discovery to establish COTS spend baseline by domain, platform engineering headcount model, migration cost estimates, and break-even window. Build the real business case.

3 Architect Governance Before Code

Define agent identity, authority taxonomy, HITL checkpoints, OSS lifecycle governance, and tiered operating model before any agent touches production. Treat DevSecOps governance as architecture; design it before you write policy.

4 Launch the DevOps Pilot

One domain. Deploy GitLab + Mattermost + Wazuh. Build the first OAAD agent crew. Establish measurable outcomes: cycle time, MTTR, deployment frequency. Demonstrate the pattern. Build the muscle.
